Appendix

Appendix figures
Appendix Figure S1. Alkaline phosphatase (AP) activity in T13-injected uteri. 
Appendix Figure S2. Pharmacological inhibition of EGFR, COX-2 and ERα don’t decrease the T13-induced expression of Hbegf and Ptgs2. 
Appendix Figure S3. LPA detection in the uterine flushing fluids from the pregnant mice. 
Appendix Figure S4. Detection of LPC species in pre-implanted blastocysts. 
Appendix Figure S5. Activation of LPA₃ induced ectodomain-shedding of HB-EGF in vitro. 
Appendix Figure S6. Uterine tissue from Lpar3 KO mice less developed in Endometriosis model. 

Appendix Methods
Appendix References
Figure S1. Alkaline phosphatase (AP) activity in T13-injected uteri.
Representative photographs of AP staining in T13-injected uteri 48 h after the injection. High AP activity was induced by T13-injection in an LPA$_3$-dependent manner. Each image is a representative from at least 3 independent experiments. Scale bar = 200 µm.
Figure S2. Pharmacological inhibition of EGFR, COX-2 and ERα don't decrease the T13-induced expression of Hbegf and Ptgs2.

Six hours after the treatment of T13 and inhibitors, each expression of Hbegf and Ptgs2 was evaluated by qRT-PCR (n = 20 for T13, n = 9 for T13 + EGFR inhibitor, n = 10 for T13 + COX-2 inhibitor and n = 13 for T13 + ERα antagonist in Hbegf; n = 9 for T13, T13 + EGFR inhibitor and T13 + ERα antagonist, n = 10 for T13 + COX-2 inhibitor in Ptgs2). Data are means ± SEM.
Figure S3

The pregnant uteri were flushed with 50 µl of saline with or without albumin. 30 µl of the flushed fluids were mixed with 70 µl methanol and then processed for LC-MS/MS analysis (n = 5 for each bar). When the uteri were flushed with the albumin-containing saline, LPA with an unsaturated fatty acid was detected. The estimated concentration of LPA in the uterine cavity is 1-2 nM, provided that the volume of uterine cavity is ~5 µl. Data are means ± SEM, n.d.: not detected.
Supplementary Figure S4. Detection of LPC species in pre-implanted blastocysts.
Ten pre-implanted embryos were mixed and subjected to lysophospholipid analysis using LC-MS/MS. A single data point was measured by two biological replicates. Representative data from two experiments with similar results were shown. Data are means + SD.
Figure S5. Activation of LPA3 induced ectodomain-shedding of HB-EGF in vitro.

LPA3 and AP-HB-EGF plasmids were co-transfected to HEK293 cells which endogenously express some protease responsible for ectodomain-shedding of HB-EGF. LPA3 was activated by LPA or T13 and then the shedding was evaluated by a method based on TGFα shedding assay (Inoue et al., 2012; see also “Materials and Methods” in the main manuscript). For each experiment, a single data point was measured by three biological replicates. Data are means ± SEM, respectively.
Figure S6

(A) Scheme of the endometriosis model. The uterine tissues from donor mice (either WT or Lpar3 KO) were minced and injected i.p. into WT recipient mice (n = 28 for WT and n = 30 for Lpar3 KO), and three weeks after, weight of endometrial tissues developed in the peritoneal cavity was determined. Eight recipient mice for WT uterine tissues and one for Lpar3 KO uterine tissues died during the three weeks. (B) Representative photographs of ectopic endometrial tissues developed in peritoneal cavity (arrow heads). (C) The weight of ectopic endometrial tissues in survived mice three weeks after the injection of endometrium. Data are means ± SEM, *P < 0.05.

Figure S6. Uterine tissue from Lpar3 KO mice less developed in Endometriosis model.

(A) Scheme of the endometriosis model. The uterine tissues from donor mice (either WT or Lpar3 KO) were minced and injected i.p. into WT recipient mice (n = 28 for WT and n = 30 for Lpar3 KO), and three weeks after, weight of endometrial tissues developed in the peritoneal cavity was determined. Eight recipient mice for WT uterine tissues and one for Lpar3 KO uterine tissues died during the three weeks. (B) Representative photographs of ectopic endometrial tissues developed in peritoneal cavity (arrow heads). (C) The weight of ectopic endometrial tissues in survived mice three weeks after the injection of endometrium. Data are means ± SEM, *P < 0.05.
Appendix Methods

Alkaline phosphatase staining
Alkaline phosphatase staining was performed as previously described (Franco et al, 2011) with some modifications. Briefly, 8 µm cryosections were fixed in 0.2% glutaraldehyde and then washed in PBS. Sections were incubated with a 100 mM Tris buffer (pH 9.5) containing 5-bromo-4-chloro-3-indolyl phosphate and nitro blue tetrazolium chloride (Roche Applied Science).

LC-MS/MS analysis of LPA and LPC
The pregnant uteri on 3.5 dpc were flushed with 50 µl of saline with or without 0.1 % bovine serum albumin (fatty acid-free, Sigma-Aldrich) through the tubal end. The flushing fluids (30 µl) were mixed with 70 µl methanol with 17:0 LPA as an internal standard. The blastocysts were recovered at 3.5 dpc from the uteri by flushing with saline through the tubal end. The recovered embryos were then collected using a glass micropipette (Drummond Scientific Company) under a dissecting microscope. After centrifugation (190 g for 5 min), the blastocysts pellets were mixed with methanol (100 µl) with 17:0 LPC as an internal standard. Each sample was homogenized for 10 min in an ultrasonic bath and centrifuged at 21,500 g for 10 min at 4 °C. The supernatant was passed through a filter (0.2 µm pore size, 4 mm inner diameter; YMC). Samples were injected into a Dionex UltiMate 3000 (Thermo Fisher Scientific) with the columns of Capcell Pak C18 (150 mm × 0.3 mm i.d., 3 µm particle size) as analytical column and Capcell Pak C18 (50 mm × 0.3 mm i.d., 3 µm particle size) as trap column. Each column was maintained at 40 °C and the mobile phase flow rate was 10 µl/min. The mobile phase was same as detailed in an earlier study (Okudaira et al, 2014). The MS system was a TSQ Quantiva (Thermo Fisher Scientific) triple quadrupole mass spectrometer equipped with a heated-electrospray ionization-II (HESI-II) source. HESI was performed in the positive mode for LPC and negative mode for LPA. Samples were analyzed in SRM mode, using the transitions of the [M+H]+ precursor ions to their product ions. The concentration of LPA in the uterine flushing fluids was calculated by comparing the peak area of each LPA species with the area of internal standard (17:0 LPA, final 70 nM in each sample).

Endometriosis model
Mouse endometriosis model was performed according to the method previously reported (Hirata et al, 2005; Tomio et al, 2013). First, both donor (Lpar3 KO or WT mice, 6–8 weeks old) and recipient mice (WT mice, 6–8 weeks old) were subjected to ovariectomy to eliminate the effects of endogenous female sex hormones. After the ovariectomy, all donor mice and recipient mice were injected s.c. with b-estradiol (100 mg/kg, Wako Pure Chemical Industries) in corn oil every week. Two weeks after the ovariectomy, uterine horns were dissected from the donor mice and minced using a scissor and a razor blade. Uterine tissue fragments suspended in PBS were injected with an 18-gauge needle into the peritoneal cavity of the recipient mice with a ratio of one donor to two recipients. Three weeks after the injection, the recipient mice were sacrificed and peritoneal endometriotic lesions were measured directly by weighing.
